

Figure S26. Stimulation effects derived from event-related average response amplitudes, pulvinar sites. For each ROI, the mean stimulation effect calculated as difference between stimulation and no stimulation response amplitudes (gray bar) and task condition-specific stimulation effects (green, red and blue bars) are shown together with the results of two-way ANOVA across trials (asterisk –significant effect of stimulation, filled circle –significant effect of task, cross –significant interaction, $p < 0.05$).
